(57) **ABSTRACT**

Provided are novel building integrable photovoltaic (BIP) modules and methods of fabricating thereof. A module may be fabricated from an insert having one or more photovoltaic cells by electrically interconnecting and mechanically integrating one or more connectors with the insert. Each connector may have one or more conductive elements, such as metal sockets and/or pins. At least two of all conductive elements are electrically connected to the photovoltaic cells using, for example, bus bars. These and other electrical components are electrically insulated using a temperature resistant material having a Relative Temperature Index (RTI) of at least about 115° C. The insulation may be provided before or during module fabrication by, for example, providing a prefabricated insulating housing and/or injection molding the temperature resistant material. The temperature resistant material and/or other materials may be used for mechanical integration of the one or more connectors with the insert.

ELECTRICAL CONNECTORS OF BUILDING INTEGRABLE PHOTOVOLTAIC MODULES

BACKGROUND

Photovoltaic cells are widely used for electricity generation with one or more photovoltaic cells typically sealed within and interconnected in a module. Multiple modules may be arranged into photovoltaic arrays used to convert solar energy into electricity by the photovoltaic effect. Arrays can be installed on building rooftops and are used to provide electricity to the buildings and to the general grid.

SUMMARY

Provided are novel building integrable photovoltaic (BIP) modules and methods of fabricating thereof. A module may be fabricated from an insert having one or more photovoltaic cells by electrically interconnecting and mechanically integrating one or more connectors with the insert. Each connector has one or more conductive elements, such as metal sockets and/or pins. At least two conductive elements are electrically connected to the photovoltaic cells using, for example, bus bars. These and other electrical components are electrically insulated using a temperature resistant material having a Relative Temperature Index (RTI) of at least about 115° C. or, at least in some cases at least about 120° C., 125° C., 130° C., 135° C. or more. The RTI is the maximum service temperature at which the critical properties of a material will remain within acceptable limits over a long period of time. The applicable standard is UL 746B, incorporated herein by reference. The insulation may be provided before or during module fabrication by, for example, providing a prefabricated insulating housing and/or injection molding the temperature resistant material. The temperature resistant material and/or other materials may be used for mechanical integration of the one or more connectors with the insert.

In certain embodiments, a method of fabricating a BIP module involves providing a photovoltaic module insert having one or more electrically interconnected photovoltaic cells and one or more bus bars extending away from at least one side of the insert. Two of the bus bars are electrically connected to the photovoltaic cells. A connector member having one or more conductive elements is also provided. The method continues with electrically connecting at least one conductive element to at least one bus bar. The method continues with forming a connector body around at least a portion of the connector member by injection molding a polymeric material, which may be a temperature resistant material and/or other some other material. In either case, the resulting BIP module includes a temperature resistant material that has an RTI of at least about 115° C., which covers at least the conductive element and the bus bar.

In certain embodiments, a temperature resistant material includes one or more of rigid materials. Some examples of rigid materials include polyethylene terephthalate (e.g., RYNITE® available from Du Pont in Wilmington, Del.), polybutylene terephthalate (e.g., CRASTIN® also available from Du Pont), nylon in any of its engineered formulations of Nylon 6 and Nylon 66, polyphenylene sulfide (e.g., RYTON® available from Chevron Phillips in The Woodlands, Tex.), polyamide (e.g., ZYTEL® available from DuPont), polycarbonate (PC), polyester (PE), polypropylene (PP), and polyvinyl chloride (PVC) and weather able engineering thermoplastics such as polyphenylene oxide (PPO), polymethyl methacrylate, polyphenylene (PPE), styrene-acrylonitrile (SAN), polystyrene and blends based on those

materials. Furthermore, weatherable thermosetting polymers, such as unsaturated polyester (UP) and epoxy, may be used. The properties of these materials listed above may be enhanced with the addition of fire retardants, color pigments, anti-tracking, and/or ignition resistant materials. In addition, glass or mineral fibers powders and/or spheres may be used to enhance the structural integrity, surface properties, and/or weight reduction. The materials may also include additives such as anti-oxidants, moisture scavengers, blowing or foaming agents, mold release additives, or other plastic additives. One or more of these additives may be also a part of other non-temperature resistant materials used in forming a connector body or an overmold covering at least a portion of the connector body. In more specific embodiments, the material has an RTI of at least about 125° C. or even an RTI of at least about 135° C.

In certain embodiments, a temperature resistant material may be at least partially enclosed in one or more of flexible materials. Some examples of flexible materials include polyethylene, polypropylene, thermoplastic olefins, thermoplastic rubber, thermoplastic elastomer, ethylene propylene diene, monomer (EPDM), fluoroelastomers or thermoplastic vulcanizates (TPV), and flexible cast thermoset materials, such as urethanes or silicones. In general, various flexible thermoplastic elastomers that have suitable thermally durable behavior may be used. Some specific examples include SANTOPRENE® (Supplied by Exxon Mobil in Houston, Tex.), HIPEX® (Supplied by Sivaco in Santa Clara, Calif.), EFLEX® (Supplied by E-Polymers Co., Ltd. In Seoul, Korea), ENFLEX® (Supplied by Enplast Limited in Longford, Ireland), EXCELINK® (Supplied by JSR Corporation in Tokyo, Japan), SYNOPRENE® (Supplied by Synoprene Polymers Pvt. Ltd. in Mumbai, India), Elastron® (Supplied by Elastron Kimya in Kocaeli, Turkey). Some additional examples include nitrile butadiene rubber (e.g., KRYNAC® (available from Lanxess in Maharashtra, India), NIPOL® (available from Zeon Chemicals in Louisville, Ky.) or NYSYN® (available from Copolymer Rubber & Chemicals in Baton Rouge, La.)), hydrogenated nitrile butadiene rubber (e.g., THERBAN® (available from Lanxess in Maharashtra, India), ZETPOL® (available from Zeon Chemicals in Louisville, Ky.)), and tetra-fluoro-ethylene-propylene (e.g., AFLAS® (Asahi Glass in Tokyo, Japan) and DYNEON BRF® (available from 3M in St. Paul, Minn.) and VITON VTR® (available from DuPont Performance Polymers in Wilmington, Del.)).

Some materials described above and elsewhere in this document may include engineered polymers, which are specifically formulated to meet certain requirements specific for photovoltaic applications. For example, certain hybrid block co-polymers may be used.

In more specific embodiments, a provided connector member includes a prefabricated insulating housing that at least initially mechanically supports and/or electrically insulates one or more conductive elements. The housing may be made from or include one or more temperature resistant materials described above. In even more specific embodiments, a connector body is formed around the insulating housing by injection molding one or more of the flexible materials described above. Other more specific examples are listed above. This connector body extends over at least a portion of the photovoltaic module insert to provide mechanical support to the connector with respect to the insert. In certain embodiments, a housing includes one or more extension flaps forming an insulating sleeve around one or more bus bars extending outside the insert and connected to the one or more conductive elements inside the insulating housing. In other embodi-

ments, a fabrication process involves insulating such portions of the bus bars and/or other electrical components prior to forming the rest of the connector body. This insulation component may be formed by injection molding one or more temperature resistant materials.

In certain embodiments, a connector body is formed using a temperature resistant material without any additional materials molded over the connector body. The connector body may extend over at least a portion of the insert to support the connector body with respect to the insert. In other embodiments, fabrication of a module involves forming an additional module overmold over at least a portion of the connector body made from the temperature resistance material. The module overmold extends over at least a portion of the insert. In certain specific embodiments, both the overmold and the connector body extend over the insert. The overmold may be made from one or more of the flexible materials listed above.

In certain embodiments, a connector body includes a cavity with a conductive element positioned inside the cavity, e.g., forming a conductive socket inside the cavity for receiving a conductive pin of another connector. The connector body may also include a seal positioned around the cavity's opening. The seal may be formed by injection molding of one or more of the flexible materials listed above. Other more specific examples are listed above. When two connectors engage with each other, one or two seals (e.g., one seal on each connector) protect the conductive elements of the two connectors from contaminations. In some embodiments, electrically connecting a conductive element of a connector member to a bus bar of the insert involves aligning the connector member with respect to the insert. More specifically, the conductive element is aligned with respect to the bus bar. This alignment may be substantially maintained during one or more later operations, for example, during formation of a connector body. Electrically connecting the conductive element to the bus bar may involve one or more of the following techniques: resistance welding, ultrasonic welding, laser welding, and soldering.

Also provided are examples of BIP modules for use on building structures, such as rooftops. In certain embodiments, a BIP module includes an insert having one or more electrically interconnected photovoltaic cells and one or more bus bars extending away from the insert. Two of these bus bars are electrically connected to the cells. The BIP module also includes one or more connectors including conductive elements. At least two of these conductive elements electrically connected to the cells using two or more of the bus bars. One of the connectors may have a connector body formed around its one or more conductive elements and portions of the bus bars extending from the inserts and making electrical connections to the conductive elements. The connector body may be made from a temperature resistant material having an RTI of at least about 115° C. or, more particularly, an RTI of at least about 125° C.

In certain embodiments, a portion of a connector body or an overmold over a connector body may be made from one or more of flexible materials listed above. Other more specific examples are listed above. In general, these materials may be formed around a portion of the connector body made from one or more of the temperature resistant materials or a prefabricated connector described above. An insert of the BIP module may have one or more ventilation channels for cooling the module during its operation. In certain embodiments, an insert has a bus bar that is not electrically connected to the photovoltaic cells. This bus bar may extend from one side of the module to another and be used, for example, for making in-series electrical connections with other modules. This bus

bar may be electrically connected to a separate conductive element of a connector. Another conductive element of the same connector may be electrically connected to the photovoltaic cells.

These and other aspects of the invention are described further below with reference to the figures.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is a schematic cross-sectional side view of a building integrable photovoltaic (BIP) module in accordance with certain embodiments.

FIG. 2 is a schematic top view of a BIP module in accordance with certain embodiments.

FIG. 3 illustrates a subset of a photovoltaic array that includes six BIP modules in accordance with certain embodiments.

FIG. 4 is a schematic illustration of a photovoltaic array installed on a rooftop of a building structure in accordance with certain embodiments.

FIG. 5 is a schematic representation of a photovoltaic module having electrically interconnected photovoltaic cells in accordance with certain embodiments.

FIG. 6 is a schematic electrical diagram of a photovoltaic array having three BIP modules interconnected in series in accordance with certain embodiments.

FIG. 7 is a schematic electrical diagram of another photovoltaic array having three BIP modules interconnected in parallel in accordance with other embodiments.

FIGS. 8A-8C are schematic cross-sectional views of two connectors configured for interconnection with each other in accordance with certain embodiments.

FIG. 9 is a process flowchart corresponding to a method of fabricating a BIP module in accordance with certain embodiments.

FIG. 10A is a schematic representation of one example a BIP module having a connector made entirely from a temperature resistant material in accordance with certain embodiments.

FIG. 10B is a schematic representation of another example of a BIP module having a connector made from a prefabricated insulating housing and an overmold formed around the housing in accordance with certain embodiments.

FIG. 10C is a schematic representation of yet another example of a BIP module having an inner portion of the connector made from a temperature resistant material and an outer portion of the connector made from a different material in accordance with certain embodiments.

FIG. 11 illustrates a schematic illustration of an alignment fixture at different stages during the module fabrication process in accordance with certain embodiments.

FIG. 12 is a schematic illustration of a connector member having two flat conductive elements in accordance with certain embodiments.

DETAILED DESCRIPTION OF EXAMPLE EMBODIMENTS

In the following description, numerous specific details are set forth in order to provide a thorough understanding of the present invention. The present invention may be practiced without some or all of these specific details. In other instances, well known process operations have not been described in detail to not unnecessarily obscure the present invention. While the invention will be described in conjunction with the specific embodiments, it will be understood that it is not intended to limit the invention to the embodiments.

Building-integrable photovoltaic (BIP) modules are defined as specially configured photovoltaic modules that are used for integration into building structures in various parts of buildings, such as rooftops, skylights, or facades. In certain examples, BIP modules replace conventional building materials, such as asphalt shingles. Unlike traditional photovoltaic systems, BIP modules often do not require separate mounting hardware. As such, installed BIP modules provide substantial savings over more traditional systems in terms of building materials and labor costs. For example, a substantial part of traditional asphalt roof shingles may be replaced by “photo-voltaic shingles.” In certain embodiments, photovoltaic shingles are installed on the same base roof structures as the asphalt shingles. In fact, a rooftop may be covered by a combination of the asphalt and photovoltaic shingles. In certain embodiments, BIP modules are shaped like one or a collection of asphalt shingles. BIP modules may look and act much like the asphalt shingles while producing electricity in addition to protecting the underlying building structures from the environment. In certain embodiments, BIP modules may be about 14 (e.g., 13.25) inches by about 40 (e.g., 39.375) inches in size and may be stapled directly to the roof deck through water barrier roofing cloth, for example. Generally, only a portion of the photovoltaic shingle is exposed, while the remaining portion is covered by other shingles. The exposed portion is referred to as the “shingle exposure”, while the covered portion is referred to as the “flap.” For example, the shingle exposure of a 13.25 inch by 39.375 inch shingle may be only about 5 inches wide or, in some embodiments, about 5.625 inches wide. The length of the shingle exposure in some of these embodiments may be 36 inches or about 39.375 inches (if side skirts are not used, for example). Other dimensions of photovoltaic shingles may be used as well.

BIP modules described herein include designs capable of withstanding higher operating temperatures typical for rooftops and other operating environments. Electrical components of connectors and/or inserts are electrically insulated using a temperature resistant material having a Relative Temperature Index (RTI) of at least about 115° C. In certain embodiments, higher RTI rated materials are used. An RTI is defined as the maximum service temperature at which certain properties of the material remain within predetermined limits over a period of time. More specifically, an RTI may be defined as a maximum service temperature for a material where a class of critical property will not be unacceptably compromised through chemical thermal degradation. This time frame may span over the reasonable life of an electrical product, relative to a reference material. For example, a polymer with 115° C. RTI rating may preserve at least 50% of its dielectric strength, tensile impact strength, and/or tensile strength for the entire operating period of a BIP module (e.g., 15 or 20 years). Some examples of rigid materials that have such RTI ratings are presented above. However, RTI rated materials may be expensive and often do not provide all needed properties, such as mechanical support, ductility, conformability, low cost, UV stability, and other characteristics. Other materials may also be used to form an overmold to provide additional mechanical support and/or electrical insulation. In certain embodiments, polyethylene, polypropylene, and/or thermoplastic rubber is injection molded over the temperature resistant materials and at least a portion of the insert.

Furthermore, embodiments of BIP module designs provided herein are configured for rapid installation on building structures, such as building rooftops, providing substantial labor savings. In certain embodiments, mechanical alignment of two BIP modules in the same row also results in electrical

interconnection of the two modules. In specific embodiments, connectors are used to align one BIP module with respect to another.

For purposes of this document, a BIP module is defined as an assembled unit ready for installation on a building structure. One particular example of a BIP module is a photovoltaic shingle for installation on roof structures. A BIP module may be configured for direct connection to other BIP modules (i.e., connected only via BIP-integrated electrical connectors) or indirect connection to other BIP modules (i.e., connection via a separate connector not integrated with a BIP module). A BIP module typically is fabricated using a photovoltaic insert that has two or more integrated electrical connectors. Other components of BIP modules may include moisture flaps (e.g., a top flap, which is sometimes referred to as a “top lap” and/or a side skirt), mechanical support sheets or components, sealing components, heat transfer features (e.g., ventilation channels in a support sheet), and the like.

A photovoltaic insert is defined as a prefabricated photovoltaic subassembly that forms part of a BIP module and used for its fabrication. The insert includes one or more photovoltaic cells, e.g., multiple electrically interconnected photovoltaic cells, sealing sheets enclosing the cell or cells, cell-cell interconnectors (if necessary), electrical contacts extending out of the sealing sheets for establishing electrical connections with the photovoltaic cells and other electrical components of the insert. In certain embodiments, the insert includes one or more bus bars, or other electrically conductive components configured to carry current through an insert or BIP module. A bus bar may be made of a strip of highly conductive material, typically metal, for example copper, that is configured to carry a rated amount of current in the context of its operating environment. An insert may include one or more bus bars that extends from one edge of the insert to another without having any direct electrical connections to the photovoltaic cells. An insert may also include one or more bus bars that are configured for or in direct electrical communication with one or more photovoltaic cells of the insert.

To provide a better understanding of various features of BIP modules and methods of integrating connectors with photovoltaic inserts during module fabrication, some examples of BIP modules will now be briefly described. FIG. 1 is a schematic cross-sectional end view (line 1-1 in FIG. 2 indicates the position of this cross-section) of a BIP module 100 in accordance with certain embodiments. BIP module 100 may have one or more photovoltaic cells 102 that are electrically interconnected. Photovoltaic cells 102 may be interconnected in parallel, in series, or in various combinations of these. Examples of photovoltaic cells include copper indium gallium selenide (CIGS) cells, cadmium-telluride (Cd—Te) cells, amorphous silicon (a-Si) cells, micro-crystalline silicon cells, crystalline silicon (c-Si) cells, gallium arsenide multi-junction cells, light adsorbing dye cells, organic polymer cells, and other types of photovoltaic cells.

Photovoltaic cell 102 has a photovoltaic layer that generates a voltage when exposed to sunlight. In certain embodiments, the photovoltaic layer includes a semiconductor junction. The photovoltaic layer may be positioned adjacent to a back conductive layer, which, in certain embodiments, is a thin layer of molybdenum, niobium, copper, and/or silver. Photovoltaic cell 102 may also include a conductive substrate, such as stainless steel foil, titanium foil, copper foil, aluminum foil, or beryllium foil. Another example includes a conductive oxide or metallic deposition over a polymer film, such as polyimide. In certain embodiments, a substrate has a thickness of between about 2 mils and 50 mils (e.g., about 10 mils), with other thicknesses also within the scope. Photovol-

taic cell **102** may also include a top conductive layer. This layer typically includes one or more transparent conductive oxides (TCO), such as zinc oxide, aluminum-doped zinc oxide (AZO), indium tin oxide (ITO), and gallium doped zinc oxide. A typical thickness of a top conductive layer is between about 100 nanometers to 1,000 nanometers (e.g., between about 200 nanometers and 800 nanometers), with other thicknesses within the scope.

In certain embodiments, photovoltaic cells **102** are interconnected using one or more current collectors (not shown). The current collector may be attached and configured to collect electrical currents from the top conductive layer. The current collector may also provide electrical connections to adjacent cells as further described with reference to FIG. 5, below. The current collector includes a conductive component (e.g., an electrical trace or wire) that contacts the top conductive layer (e.g., a TCO layer). The current collector may further include a top carrier film and/or a bottom carrier film, which may be made from transparent insulating materials to prevent electrical shorts with other elements of the cell and/or module. In certain embodiments, a bus bar is attached directly to the substrate of a photovoltaic cell. A bus bar may also be attached directly to the conductive component of the current collector. For example, a set of photovoltaic cells may be electrically interconnected in series with multiple current collectors (or other interconnecting wires). One bus bar may be connected to a substrate of a cell at one end of this set, while another bus bar may be connected to a current collector at another end.

Photovoltaic cells **102** may be electrically and environmentally insulated between a front light-incident sealing sheet **104** and a back sealing sheet **106**. Examples of sealing sheets include glass, polyethylene, polyethylene terephthalate (PET), polypropylene, polybutylene, polybutylene terephthalate (PBT), polyphenylene oxide (PPO), polyphenylene sulfide (PPS), polystyrene, polycarbonates (PC), ethylene-vinyl acetate (EVA), fluoropolymers (e.g., polyvinyl fluoride (PVF), polyvinylidene fluoride (PVDF), ethylene-terafluoroethylene (ETFE), fluorinated ethylene-propylene (FEP), perfluoroalkoxy (PFA) and polychlorotrifluoroethane (PCTFE)), acrylics (e.g., poly(methyl methacrylate)), silicones (e.g., silicone polyesters), and/or polyvinyl chloride (PVC), as well as multilayer laminates and co-extrusions of these materials. A typical thickness of a sealing sheet is between about 5 mils and 100 mils or, more specifically, between about 10 mils and 50 mils. In certain embodiments, a back sealing sheet includes a metallized layer to improve water permeability characteristics of the sealing sheet. For example, a metal foil may be positioned in between two insulating layers to form a composite back sealing sheet. In certain embodiments, a module has an encapsulant layer positioned between one or both sealing sheets **104**, **106** and photovoltaic cells **102**. Examples of encapsulant layer materials include non-olefin thermoplastic polymers or thermal polymer olefin (TPO), such as polyethylene (e.g., a linear low density polyethylene, polypropylene, polybutylene, polyethylene terephthalate (PET), polybutylene terephthalate (PBT), polystyrene, polycarbonates, fluoropolymers, acrylics, ionomers, silicones, and combinations thereof.

BIP module **100** may also include an edge seal **105** that surrounds photovoltaic cells **102**. Edge seal **105** may be used to secure front sheet **104** to back sheet **106** and/or to prevent moisture from penetrating in between these two sheets. Edge seal **105** may be made from certain organic or inorganic materials that have low inherent water vapor transmission rates (WVTR), e.g., typically less than 1-2 g/m²/day. In certain embodiments, edge seal **105** is configured to absorb

moisture from inside the module in addition to preventing moisture ingress into the module. For example, a butyl-rubber containing moisture getter or desiccant may be added to edge seal **105**. In certain embodiments, a portion of edge seal **105** that contacts electrical components (e.g., bus bars) of BIP module **100** is made from a thermally resistant polymeric material. Various examples of thermally resistant materials and RTI ratings are further described below.

BIP module **100** may also have a support sheet **108** attached to back side sealing sheet **106**. The attachment may be provided by a support edge **109**, which, in certain embodiments, is a part of support sheet **108**. Support sheets may be made, for example, from rigid materials. Some examples of rigid materials include polyethylene terephthalate (e.g., RYNITE® available from Du Pont in Wilmington, Del.), polybutylene terephthalate (e.g., CRASTIN® also available from Du Pont), nylon in any of its engineered formulations of Nylon 6 and Nylon 66, polyphenylene sulfide (e.g., RYTON® available from Chevron Phillips in The Woodlands, Tex.), polyamide (e.g., ZYTEL® available from DuPont), polycarbonate (PC), polyester (PE), polypropylene (PP), and polyvinyl chloride (PVC) and weatherable engineering thermoplastics such as polyphenylene oxide (PPO), polymethyl methacrylate, polyphenylene (PPE), styrene-acrylonitrile (SAN), polystyrene and blends based on those materials. Furthermore, weatherable thermosetting polymers, such as unsaturated polyester (UP) and epoxy, may be used. The properties of these materials listed above may be enhanced with the addition of fire retardants, color pigments, anti-tracking, and/or ignition resistant materials. In addition, glass or mineral fibers powders and/or spheres may be used to enhance the structural integrity, surface properties, and/or weight reduction. The materials may also include additives such as anti-oxidants, moisture scavengers, blowing or foaming agents, mold release additives, or other plastic additives.

In certain embodiments, support sheet **108** may be attached to back sheet **106** without a separate support edge or other separate supporting element. For example, support sheet **108** and back sheet **106** may be laminated together or support sheet **108** may be formed (e.g., by injection molding) over back sheet **106**. In other embodiments back sealing sheet **106** serves as a support sheet. In this case, the same element used to seal photovoltaic cells **102** may be positioned over and contact a roof structure (not shown). Support sheet **108** may have one or more ventilation channels **110** to allow for air to flow between BIP module **100** and a building surface, e.g., a roof-deck or a water resistant underlayment/membrane on top of the roof deck. Ventilation channels **110** may be used for cooling BIP module during its operation. For example, it has been found that each 1° C. of heating from an optimal operating temperature of a typical CIGS cell causes the efficiency loss of about 0.33% to 0.5%.

BIP module **100** has one or more electrical connectors **112** for electrically connecting BIP module **100** to other BIP modules and array components, such as an inverter and/or a battery pack. In certain embodiments, BIP module **100** has two electrical connectors **112** positioned on opposite sides (e.g., the short or minor sides of a rectangular module) of BIP module **100**, as for example shown in FIGS. 1 and 2, for example. Each one of two electrical connectors **112** has at least one conductive element electrically connected to photovoltaic cells **102**. In certain embodiments, electrical connectors **112** have additional conductive elements, which may or may not be directly connected to photovoltaic cells **102**. For example, each of two connectors **112** may have two conductive elements, one of which is electrically connected to photovoltaic cells **102**, while the other is electrically con-

nected to a bus bar (not shown) passing through BIP module 100. This and other examples are described in more detail in the context of FIGS. 6 and 7. In general, regardless of the number of connectors 112 attached to BIP module 100, at least two conductive elements of these connectors 112 are electrically connected to photovoltaic cells 102.

FIG. 2 is a schematic top view of BIP module 100 in accordance with certain embodiments. Support sheet 108 is shown to have a side skirt 204 and a top flap 206 extending beyond a BIP module boundary 202. Side skirt 204 is sometimes referred to as a side flap, while top flap 206 is sometimes referred to as a top lap. In certain embodiments, BIP module 100 does not include side flap 204. BIP module boundary 202 is defined as an area of BIP module 100 that does not extend under other BIP modules or similar building materials (e.g., roofing shingles) after installation. BIP module boundary 202 includes photovoltaic cells 102. Generally, it is desirable to maximize the ratio of the exposed area of photovoltaic cells 102 to BIP module boundary 202 in order to maximize the “working area” of BIP module 100. It should be noted that, after installation, flaps of other BIP modules typically extend under BIP module boundary 202. In a similar manner, after installation, side flap 204 of BIP module 100 may extend underneath another BIP module positioned on the left (in the same row) of BIP module 100 creating an overlap for moisture sealing. Top flap 206 may extend underneath one or more BIP modules positioned above BIP module 100. Arrangements of BIP modules in an array will now be described in more detail with reference to FIGS. 3 and 4.

FIG. 3 illustrates a photovoltaic array 300 or, more specifically a portion of a photovoltaic array, which includes six BIP modules 100a-100f arranged in three different rows extending along horizontal rooflines in accordance with certain embodiments. Installation of BIP modules 100a-100f generally starts from a bottom roofline 302 so that the top flaps of BIP modules 100a-100f can be overlapped with another row of BIP modules. If a side flap is used, then the position of the side flap (i.e., a left flap or a right flap) determines which bottom corner should be the starting corner for the installation of the array. For example, if a BIP module has a top flap and a right-side flap, then installation may start from the bottom left corner of the roof or of the photovoltaic array. Another BIP module installed later in the same row and on the right of the initial BIP module will overlap the side flap of the initial BIP module. Furthermore, one or more BIP modules installed in a row above will overlap the top flap of the initial BIP module. This overlap of a BIP module with a flap of another BIP module creates a moisture barrier.

FIG. 4 is a schematic illustration of a photovoltaic array 400 installed on a rooftop 402 of a building structure 404 for protecting building structure 404 from the environment as well as producing electricity in accordance with certain embodiments. Multiple BIP modules 100 are shown to fully cover one side of rooftop 402 (e.g., a south side or the side that receives the most sun). In other embodiments, multiple sides of rooftop 402 are used for a photovoltaic array. Furthermore, some portions of rooftop 402 may be covered with conventional roofing materials (e.g., asphalt shingles). As such, BIP modules 100 may also be used in combination with other roofing materials (e.g., asphalt shingles) and cover only a portion of rooftop. Generally, BIP modules 100 may be used on steep sloped to low slope rooftops. For example, the rooftops may have a slope of at least about 2.5-to-12 or, in many embodiments, at least about 3-to-12.

Multiple BIP modules 100 may be interconnected in series and/or in parallel with each other. For example, photovoltaic array 400 may have sets of BIP modules 100 interconnected

in series with each other (i.e., electrical connections among multiple photovoltaic modules within one set), while these sets are interconnected in parallel with each other (i.e., electrical connections among multiple sets in one array). Photovoltaic array 400 may be used to supply electricity to building structure 404 and/or to an electrical grid. In certain embodiments, photovoltaic array 400 includes an inverter 406 and/or a battery pack 408. Inverter 406 is used for converting a direct current (DC) generated by BIP modules 100 into an alternating current (AC). Inverter 406 may be also configured to adjust a voltage provided by BIP modules 100 or sets of BIP modules 100 to a level that can be utilized by building structure 404 or by a power grid. In certain embodiments, inverter 406 is rated up to 600 volts DC input or even up to 1000 volts DC, and/or up to 10 kW power. Examples of inverters include a photovoltaic static inverter (e.g., BWT10240-Gridtec 10, available from Trace Technologies in Livermore, Calif.) and a string inverter (e.g. Sunny Boy RTM.2500 available from SMA America in Grass Valley, Calif.). In certain embodiments, BIP modules may include integrated inverters, i.e., “on module” inverters. These inverters may be used in addition to or instead of external inverter 406. Battery pack 408 is used to balance electric power output and consumption.

FIG. 5 is a schematic representation of a photovoltaic module insert 500 illustrating photovoltaic cells 504 electrically interconnected in series using current collectors/interconnecting wires 506 in accordance with certain embodiments. Often individual cells do not provide an adequate output voltage. For example, a typical voltage output of an individual CIGS cell is only between 0.4V and 0.7V. To increase voltage output, photovoltaic cells 504 may be electrically interconnected in series for example, shown in FIG. 5 and/or include “on module” inverters (not shown). Current collectors/interconnecting wires 506 may also be used to provide uniform current distribution and collection from one or both contact layers.

As shown in FIG. 5, each pair of photovoltaic cells 504 has one interconnecting wire positioned in between the two cells and extending over a front side of one cell and over a back side of the adjacent cell. For example, a top interconnecting wire 506 in FIG. 5 extends over the front light-incident side of cell 504 and under the back side of the adjacent cell. In the figure, the interconnecting wires 506 also collect current from the TCO layer and provide uniform current distribution, and may be referred to herein as current collectors. In other embodiments, separate components are used to for current collection and cell-cell interconnection. End cell 513 has a current collector 514 that is positioned over the light incident side of cell 513 but does not connect to another cell. Current collector 514 connects cell 513 to a bus bar 510. Another bus bar 508 may be connected directly to the substrate of the cell 504 (i.e., the back side of cell 504). In another embodiment, a bus bar may be welded to a wire or other component underlying the substrate. In the configuration shown in FIG. 5, a voltage between bus bars 508 and 510 equals a sum of all cell voltages in insert 500. Another bus bar 512 passes through insert 500 without making direct electrical connections to any photovoltaic cells 504. This bus bar 512 may be used for electrically interconnecting this insert in series without other inserts as further described below with reference to FIG. 6. Similar current collectors/interconnecting wires may be used to interconnect individual cells or set of cells in parallel (not shown).

BIP modules themselves may be interconnected in series to increase a voltage of a subset of modules or even an entire array. FIG. 6 illustrates a schematic electrical diagram of a photovoltaic array 600 having three BIP modules 602a-602c interconnected in series using module connectors 605a, 605b,

11

and **606** in accordance with certain embodiments. A voltage output of this three-module array **600** is a sum of the voltage outputs of three modules **602a-602c**. Each module connector **605a** and **605b** shown in FIG. 6 may be a combination of two module connectors of BIP modules **602a-602c**. These embodiments are further described with reference to FIGS. **8A-8C**. In other words, there may be no separate components electrically interconnecting two adjacent BIP modules, with the connection instead established by engaging two connectors installed on the two respective modules. In other embodiments, separate connector components (i.e., not integrated into or installed on BIP modules) may be used for connecting module connectors of two adjacent modules.

Module connector **606** may be a special separate connector component that is connected to one module only. It may be used to electrically interconnect two or more conductive elements of the same module connector.

Sometimes BIP modules may need to be electrically interconnected in parallel. FIG. 7 illustrates a schematic electrical diagram of a photovoltaic array **700** having three BIP modules **702a-702c** interconnected in parallel using module connectors **705a** and **705b** in accordance with certain embodiments. Each module may have two bus bars extending through the module, i.e., a “top” bus bar **711** and a “bottom” bus bar **713** as shown in FIG. 7. Top bus bars **711** of each module are connected to right electrical leads **704a, 704b**, and **704c** of the modules, while bottom bus bars **713** are connected to left electrical leads **703a, 703b**, and **703c**. A voltage between the top bus bars **711** and bottom bus bars **713** is therefore the same along the entire row of BIP modules **702a-702c**.

FIG. 8A is a schematic cross-sectional side view of two connectors **800** and **815** configured for interconnection with each other, in accordance with certain embodiments. For simplicity, the two connectors are referred to as a female connector **800** and a male connector **815**. Each of the two connectors **800** and **815** is shown attached to its own photovoltaic insert, which includes photovoltaic cells **802** and one or more sealing sheets **804**. Connectors **800** and **815** include conductive elements **808b** and **818b**, respectively, which are shown to be electrically connected to photovoltaic cells **802** using bus bars **806** and **816**, respectively.

In certain embodiments, a conductive element of one connector (e.g., conductive element **808b** of female connector **800**) is shaped like a socket/cavity and configured for receiving and tight fitting a corresponding conductive element of another connector (e.g., conductive element **818b** of male connector **815**). Specifically, conductive element **808b** is shown forming a cavity **809b**. This tight fitting and contact in turn establishes an electrical connection between the two conductive elements **808b** and **818b**. Accordingly, conductive element **818b** of male connector **815** may be shaped like a pin (e.g., a round pin or a flat rectangular pin). A socket and/or a pin may have protrusions (not shown) extending towards each other (e.g., spring loaded tabs) to further minimize the electrical contact resistance by increasing the overall contact area. In addition, the contacts may be fluted to increase the likelihood of good electrical contact at multiple points (e.g., the flutes guarantee at least as many hot spot asperities of current flow as there are flutes).

In certain embodiments, connectors do not have a cavity-pin design as shown in FIGS. **8A-8C**. Instead, an electrical connection may be established when two substantially flat surfaces contact each other. Conductive elements may be substantially flat or have some topography designed to increase a contact surface over the same projection boundary and/or to increase contact force at least in some areas.

12

Examples of such surface topography features include multiple pin-type or rib-type elevations or recesses.

In certain embodiments, one or more connectors attached to a BIP module have a “touch free” design, which means that an installer can not accidentally touch conductive elements or any other electrical elements of these connectors during handling of the BIP module. For example, conductive elements may be positioned inside relatively narrow cavities. The openings of these cavities are too small for a finger to accidentally come in to contact with the conductive elements inside the cavities. One such example is shown in FIG. 8A where male connector **815** has a cavity **819b** formed by connector body **820** around its conductive pin **818b**. While cavity **819b** may be sufficiently small to ensure a “touch free” designed as explained above, it is still large enough to accommodate a portion of connector body **810** of female connector **800**. In certain embodiments, connector bodies **810** and **820** have interlocking features (not shown) that are configured to keep the two connectors **800** and **815** connected and prevent connector body **810** from sliding out of cavity **819b**. Examples of interlocking features include latches, threads, and various recess-protrusion combinations.

FIG. 8B is schematic plan view of female connector **800** and male connector **815**, in accordance with certain embodiments. Each connector **800, 815** is shown with two conductive elements (i.e., conductive sockets **808a** and **808b** in connector **800** and conductive pins **818a** and **818b** in connector **815**). One conductive element (e.g., socket **808b** and pin **818b**) of each connector is shown to be electrically connected to photovoltaic cells **802**. Another conductive element of each connector **800, 815** may be connected to bus bars (e.g., bus bars **809** and **819**) that do not have an immediate electrical connection to photovoltaic cells **802** of their respective BIP module (the extended electrical connection may exist by virtue of a complete electrical circuit).

As shown, sockets **808a** and **808b** may have their own designated inner seals **812a** and **812b**. Inner seals **812a** and **812b** are designed to provide more immediate protection to conductive elements **808a** and **818a** after connecting the two connectors **800, 815**. As such, inner seals **812a** and **812b** are positioned near inner cavities of sockets **808a** and **808b**. The profile and dimensions of pins **818a** and **818b** closely correspond to that of inner seals **812a** and **812b**. In the same or other embodiments, connectors **800, 815** have external seals **822a** and **822b**. External seals **822a** and **822b** may be used in addition to or instead of inner seals **812a** and **812b**. Various examples of seal materials and fabrication methods are described below in the context of FIG. 9. FIG. 8C is schematic front view of female connector **800** and male connector **815**, in accordance with certain embodiments. Connector pins **818a** and **818b** are shown to have round profiles. However, other profiles (e.g., square, rectangular) may also be used for pins **818a** and **818b** and conductive element cavities **808a** and **808b**.

Having described some aspects of BIP modules and, more specifically, some aspects of electrical connectors attached to photovoltaic inserts, this document will now describe various examples of a process for fabricating BIP modules. Generally, the process involves electrically connecting conductive elements of the connector member and bus wires of the insert and forming a connector body around at least a portion of the connector member and insert. FIG. 9 is a process flowchart corresponding to a process **900** for fabricating BIP modules in accordance with certain embodiments. Process **900** may start with providing a photovoltaic module insert and a connector member in operation **902**. Various examples of photovoltaic module inserts are described above, for example, in the con-

13

text of FIGS. 1 and 5. In general, an insert includes one or more electrically interconnected photovoltaic cells and two or more bus bars extending away from at least one side of the insert. At least two of these bus bars are electrically connected to the photovoltaic cells.

The connector member provided in operation 902 includes at least one conductive element. In certain embodiments, a connector member includes two or more conductive elements. The connector member may be provided with or without a prefabricated insulating housing. An insulating housing is typically made from one or more temperature resistant materials. Some examples of rigid materials with suitable thermal characteristics are provided above. In specific embodiments, an insulating housing is made from a temperature resistant material having an RTI of at least about 115° C. or, more particularly, having a RTI of at least about 125° C. In certain embodiments, an insulating housing has one or more extension flaps configured to cover and insulate a portion one or more bus bars extending out of the insert and connected to conductive elements positioned within the insulating housing. These extension flaps may be sufficiently flexible to allow accessing to the conductive elements in order to establish electrical connections between the bus bars and conductive elements.

Process 900 may proceed with establishing one or more electrical connections between one or more conductive elements of the connector member and one or more bus bars extending from the inserts (block 904). The electrical connections may be established by resistance welding, ultrasonic welding, laser welding, soldering, crimping, applying conductive adhesive, or any other suitable connection technique. In certain embodiments, a photovoltaic insert is aligned with respect to a connector member prior or during operation 904. This alignment may be maintained during subsequent operations (e.g., operations 906 and/or 908 further described below) or more generally until the connector is rigidly or semi-rigidly attached to the insert. An alignment fixture may be used for this purpose. FIG. 11 illustrates a schematic illustration of an alignment fixture 1108 in accordance with certain embodiments. Alignment fixture 1108 is shown at three stages of BIP module fabrication process 900: during establishing an initial alignment (1110), during formation of a connector body (1120), and after removal of the alignment fixture (1130).

Alignment fixture 1108 may have a reference surface 1108a for positioning a photovoltaic insert 1102 and a reference fixture 1108b for positioning a conductive element 1106. As shown during stage 1110, a portion of conductive element 1106 and a portion of bus bar 1104 may overlap in an overlap area 1112. At this stage 1110, photovoltaic insert 1102 is considered to be aligned with respect to conductive element 1106. Conductive element 1106 and bus bar 1104 may be mechanically and/or electrically interconnected with each other in overlap area 1112 using one or more attachment techniques described above.

Once the connection between conductive element 1106 and bus bar 1104 is formed, a connector body 1122 may be formed around conductive element 1106 as shown in the next stage 1120. A portion 1124 of connector body 1122 may extend over the connection area 1112 and, in certain embodiments, may extend over at least a portion of photovoltaic insert 1102. This in turn may result in connector body 1122 being rigidly or semi-rigidly attached to insert 1102. In this case, this extended portion 1124 now provides sufficient alignment between the two components. Alignment fixture 1108 may be removed at this point as shown during stage 1130.

14

Process 900 may proceed with forming a connector body in operation 906. In certain embodiments, a connector body or some parts of it comes in direct contact with electrical components of the BIP module (e.g., conductive elements of the connector member or bus bars extending outside of the insert). In these embodiments, a connector body may be formed using one or more temperature resistant materials. Some examples of rigid materials with suitable thermal characteristics are provided above. In specific embodiments, a temperature resistant material has an RTI of at least about 115° C. or, more particularly, an RTI of at least about 125° C. or even at RTI of at least about 135° C. The temperature resistant material may include one or more of the following additives: mineral fillers, glass fillers, and flame retardants.

In other embodiments, a connector body formed in operation 906 does not directly contact electrical components of the BIP module and temperature resistant materials may not be needed to form the connector body. For example, a connector member provided in operation 902 may include an insulating housing that encloses all electrical components extending outside of the photovoltaic insert (e.g., enclosing its own conductive elements and providing extensions tabs for bus wires extending outside of the insert). In these embodiments, a connector body may be made from polyethylene, polypropylene, thermoplastic rubber, thermoplastic elastomer, and ethylene propylene diene monomer. A connector body is typically formed using injection molding or other suitable techniques.

In certain embodiments, a connector body formed in operation 902 may be insufficient to provide electrical insulation and/or mechanical support. In such situations, process 900 involves operation 908 during which an overmold is formed over a portion of the connector body and, in certain embodiments, a portion of the insert. Operation 908 is optional because a connector body may be sufficient for the above recited purposes without a separate overmold. It should be noted that regardless of an overmold, a connector body may include a temperature resistant materials (e.g., provided as a part of prefabricated insulating housing and/or deposited during operation 904) and, in certain embodiments, other material (e.g., deposited during operation 904 and/or deposited during operation 906). Three specific examples are described below in the context of FIGS. 10A-10C.

Forming overmold in operation 908 may involve injection molding or any other technique. Examples of materials that can be used for an overmold include polyethylene, polypropylene, thermoplastic rubber, thermoplastic elastomer, ethylene propylene diene monomer (EPDM), various fluoroelastomers or thermoplastic vulcanizates (TPV), and flexible cast thermoset materials such as urethanes. In general, flexible thermoplastic elastomers that have suitable thermally durable behavior may be used. Some examples are provided above. An overmold generally extends over at least a portion of the photovoltaic module insert and a portion of the connector body.

Process 900 may continue with forming one or more seals around various cavities' openings in a connector body in operation 908. Various seal examples are described above in the context of FIGS. 8A-8C. Seals may be formed by injection molding or other suitable techniques. In certain embodiments, a seal may be fabricated in a separate process and inserted into the connector body during operation 908. For example, a seal may be an O-ring or more specifically a butyl rubber O-ring or flat ring.

Electrical Connector Examples

FIG. 10A is a schematic representation of one example of a BIP module 1000 in accordance with certain embodiments.

15

Some components of this assembly are similar to an assembly described above in the context of FIG. 8A. Specifically, BIP module 1000 includes one or more photovoltaic cells 802 sealed by one or more sealing sheets 804. BIP module 1000 also includes one or more bus bars 806 extending outside of sealing sheets 804 and making an electrical connection with connector element 808. The connector also has a connector body 1002 that electrically insulates and mechanically supports conductive element 808 with respect to sealing sheets 804 or more generally, an entire insert 1002. Since connector body 1002 is in direct contact with conductive element 808 and bus bar 806, it is made from one or more temperature resistant materials, such as a RTI rated materials listed above. BIP module 1000 also includes a seal 812 positioned around the opening of connector body for protecting connector element 808 from contaminants after establishing a connection with another connector. As shown in FIG. 10A, there is no additional overmold positioned around connector body 1002. Connector body 1002 provides sufficient mechanical support and electrical insulation in this example.

However, making a complete connector out of RTI rated materials may be prohibitively expensive and/or may not provide certain characteristics, such as UV stability, mechanical support, and electrical insulation. In certain embodiments, a connector may include an inner component made from one or more temperature resistant materials, such as RTI rated materials, and an outer portion made from some other materials. The inner portion contacts electrical components of the module (e.g., bus bars and conductive elements) and may be configured to fully enclose these components and prevent any contacts with an outer portion of the connector made from other materials. The inner portion may come as a prefabricated insulating housing (e.g., with flap extensions) or formed completely or partially during one or more injection molding operations during the overall BIP module fabrication process described above. For example, a prefabricated insulating housing may only cover some electrical components (e.g., conductive elements of the connector), while other (e.g., bus bars) may extend outside of the housing. A separate operation may be used to apply one or more temperature resistant materials around the remaining exposed electrical components before forming the remainder of the connector body from other non-temperature resistant materials.

FIG. 10B is a schematic representation of another example of a BIP module 1010 having a connector made from a prefabricated insulating housing 1012 and an overmold 1016 formed around housing 1012 in accordance with certain embodiments. Insulating housing 1012 is shown with extension flaps 1014 that insulate a portion of bus bar 806 extending from sealing sheets 804. Insulating housing 1012 may be partially or fully covered with overmold 1016. Overmold 1016 also extends over at least a portion of the insert 1002.

FIG. 10C is a schematic representation of yet another example of a BIP module 1020 having an inner portion 1022 of the connector made from a temperature resistant material and an outer portion 1026 of the connector made from a different material in accordance with certain embodiments. Inner portion 1022 may be configured to insulate both conductive element 808 and bus bar 806. In certain embodiments, inner portion 1022 may cover a portion of the photovoltaic insert 1002 as, for example, shown in FIG. 10C. Inner portion 1022 is made from one or more temperature resistant materials described above. Outer portion 1026 is made from other generally less expensive materials that have different functional characteristics (e.g., high UV stability).

Conclusion

16

Although the foregoing invention has been described in some detail for purposes of clarity of understanding, it will be apparent that certain changes and modifications may be practiced within the scope of the appended claims. It should be noted that there are many alternative ways of implementing the processes, systems and apparatus of the present invention. Accordingly, the present embodiments are to be considered as illustrative and not restrictive, and the invention is not to be limited to the details given herein.

What is claimed is:

1. A method of fabricating a building integrable photovoltaic module, the method comprising:

providing a photovoltaic module insert comprising one or more sealing sheets, a plurality of electrically interconnected photovoltaic cells sealed within the one or more sealing sheets, and a bus bar that is electrically connected within the one or more sealing sheets to the plurality of electrically interconnected photovoltaic cells and that extends outside the one or more sealing sheets;

providing a connector member comprising a conductive element;

electrically connecting the conductive element to the bus bar; and

after electrically connecting the conductive element to the bus bar, forming a connector body around at least a portion of the connector member by injection molding a first polymeric material,

wherein the building integrable photovoltaic module comprises a temperature resistant material having a Relative Temperature Index (RTI) of at least about 115° C., the temperature resistant material covering the conductive element and the portion of the bus bar that extends outside the one or more sealing sheets.

2. The method of claim 1, wherein the temperature resistant material is selected from the group consisting of polyethylene terephthalate, polybutylene terephthalate, nylon, polyphenylene sulfide, polyamide, polycarbonate, polyester, polypropylene, and polyvinyl chloride.

3. The method of claim 1, wherein the temperature resistant material comprises one or more additives selected from the group consisting of mineral fillers, glass fillers, and flame retardants.

4. The method of claim 1, wherein the temperature resistant material has a Relative Temperature Index (RTI) of at least about 125° C.

5. The method of claim 1, wherein the temperature resistant material is at least partially enclosed in one or more materials selected from the group consisting of polyethylene, polypropylene, thermoplastic rubber, thermoplastic elastomer, ethylene propylene diene monomer, fluor elastomers, thermoplastic vulcanizates, and flexible cast thermoset materials.

6. The method of claim 1, wherein the connector member comprises an insulating housing providing mechanical support to and/or insulating the conductive element, the insulating housing comprising the temperature resistant material.

7. The method of claim 6, wherein the first polymeric material is selected from the group consisting of polyethylene, polypropylene, thermoplastic rubber, thermoplastic elastomer, and ethylene propylene diene monomer, and wherein the connector body extends over at least a portion of the photovoltaic module insert.

8. The method of claim 6, wherein the insulating housing comprises one or more extension flaps forming an insulating sleeve around the bus bar.

17

9. The method of claim 6, further comprising insulating the bus bar, prior to forming the connector body, by injection molding the temperature resistant material around the portion of the bus bar.

10. The method of claim 1, wherein the first polymeric material comprises the temperature resistant material, and wherein the connector body extends over at least a portion of the photovoltaic module insert.

11. The method of claim 1, further comprising forming a module overmold extending over at least a portion of the photovoltaic module insert and extending over at least a portion of the connector body by injection molding a second polymeric material.

12. The method of claim 11, wherein the first polymeric material comprises the temperature resistant material, and wherein the second polymeric material comprises one or more materials selected from the group consisting of polyethylene, polypropylene, thermoplastic rubber, thermoplastic elastomer, and ethylene propylene diene monomer.

13. The method of claim 1, wherein the connector body comprises a cavity containing the conductive element positioned inside the cavity and a seal positioned around an opening of the cavity.

14. The method of claim 13, wherein the seal is formed by injection molding one or more materials selected from the group consisting of polyethylene, polypropylene, thermoplastic rubber, thermoplastic elastomer, ethylene propylene diene monomer, fluoroelastomers, thermoplastic vulcanizates, and flexible cast thermoset materials into the cavity of the connector body.

15. The method of claim 1, wherein electrically connecting comprises aligning the connector member with respect to the photovoltaic module insert, and wherein this alignment is substantially maintained during forming the connector body.

16. The method of claim 1, wherein electrically connecting comprises one or more techniques selected from the group consisting of resistance welding, ultrasonic welding, laser welding, and soldering the bus bar to the conductive element.

17. A building integrable photovoltaic module for use on building structures, the building integrable photovoltaic module comprising:

18

a photovoltaic module insert comprising one or more sealing sheets, a plurality of electrically interconnected photovoltaic cells sealed within the one or more sealing sheets, and a bus bar that is electrically connected within the one or more sealing sheets to the plurality of electrically interconnected photovoltaic cells and that extends outside the one or more sealing sheets;

a connector comprising i) a first conductive element electrically connected to the plurality of electrically interconnected photovoltaic cells by the bus bar and ii) a connector body formed around the first conductive element and the portion of the bus bar that extends outside the one or more sealing sheets, the connector body comprising a temperature resistant material having a Relative Temperature Index (RTI) of at least about 115° C. and

an overmold disposed over at least a portion of the photovoltaic module insert and extending over at least a portion of the connector body.

18. The building integrable photovoltaic module of claim 17, wherein the connector body further comprises one or more materials selected from the group consisting of polyethylene, polypropylene, thermoplastic rubber, thermoplastic elastomer, and ethylene propylene diene monomer, the one or more materials formed around the temperature resistant material and extending over at least a portion of the photovoltaic module insert.

19. The building integrable photovoltaic module of claim 17, wherein the photovoltaic module insert comprises one or more ventilation channels for cooling the photovoltaic module during operation.

20. The building integrable photovoltaic module of claim 17, wherein the photovoltaic module insert comprises a second bus bar indirectly electrically connected to the plurality of electrically interconnected photovoltaic cells, the second bus bar electrically connected to a second conductive element of the connector member.
